

Detector A (mx17_3): where do the crossing muons go? (22,270 muons, 5 mm match)

The chamber produces a signal for 100.0% of muons and reconstructs a track point for 96.0%. Genuine blindness (no signal at all) is only 0.0%. The two biggest "losses" off the 88.8% are NOT the chamber failing to see the muon: a 3.9% spark coincidence (self-quenching, zero dead time after), and a 3.1% edge / near-miss position tail — almost all within 5-10 mm, so at a 10 mm match the efficiency recovers to ~95%.
