

The low peak sits on the noise floor — and on A it holds a third of the sample

Single tracks, x view, the same numbers in all three panels. A peak 1.05 (FWHM 0.7–1.9), 36% in 1–2 C peak 1.65 (FWHM 0.8–3.9), 12% in 1–2 D peak 1.35 (FWHM 0.7–2.8), 9% in 1–2. All three chambers DO have a peak at the noise floor — the difference is how much of the sample is in it and how tight it is: A's is 3.6x taller than C's and half the width. On the linear axis the high mode never appears, because it is spread over decades; that is not a disagreement with the log panel, it is the two axes answering different questions. Left and middle are a density per unit χ^2 , which is the correct normalisation on a linear axis and the wrong one on a log axis.
