

The two bumps are short tracks and long tracks

45,421 tracks, the legs of the published pair sample (gated, angle-calibrated, DCA < 30 mm, in a trigger that made two). χ^2/dof is the mean squared residual PER WAVEFORM SAMPLE in units of that strip's own measured noise (dof = 20 × n_strips), so 1.0 is the noise floor on every chamber and the three panels are directly comparable. Both populations exist on all three; only on A does the short-track mode reach the floor, and that is what opens the gap. Chamber B carries no angle calibration and so is in no pairing and not on this figure.
