

The trigger's footprint, and its absence

PRELIMINARY

occupancy per live cell, each curve normalised to its own mean, so the comparison is of shape and not of rate

Top: along u, with the plastic-gap shadow window shaded blue and the two flank windows grey — the three windows the shadow test reads. Bottom: along v, with the bar-length limit marked. In the matched sample (red) both features are deep; in the bystander sample they are gone in A, survive in C where ~10 dead channels sit at the same u, and are unreadable in D, a quarter of whose x plane is dead. Chamber B is absent because it has no trigger-matched sample to compare against — which is the whole reason the bystander construction exists. Bins with fewer than 8 live cells are dropped rather than amplified.
