

How much the crossing amplifies

perpendicular pairs barely do; the other two do a lot

and the vertex follows it

$v_r^{xz} = \sqrt{e_1^z + e_2^z - 2e_1e_2\cos\psi/|\sin\psi|}$, exact to 1e-16

The transverse pair vertex is an algebraic function of the two legs own miss distances and the crossing angle -- not an independent look at the source. ntof_athens_26/pair_vertex_imaging | 33 runs of the condor full pass, stage-3 tracks, leg pointing cut as marked
