

Perpendicular pairs, data – null, as the D leg is cleaned (A/C leg: slope measured, not noisy; legs within 60 mm)

Transverse crossings minus the shuffled null through the same cuts, scaled by that selection's x-fit background fraction. Purple: excess; blue: deficit. Copper: the capsule at the single-track position. The excess is a vertical stripe at the capsule's x that runs the length of z, strongest where D is live (its readout is dead from $z \approx -57$ to 0 mm): the A/C leg points, the D leg contributes little more than where it hit D. Confirming the D leg leaves too few pairs to see anything. [ntof_athens_26/pair_vertex_imaging](#) | 33 runs of the condor full pass, stage-3 tracks, chambers A, C, D
